What are Sockets?

Socket Programming Framework/API

A set of **system calls** to get the service from TCP/IP protocol stack (net module in the OS kernel).

Socket Types

- The Internet is a trade-off between performance and reliability - **Can you say why?**
- Some application requires fine grained performance (example - multimedia applications), while others require reliability (example - file transfer)
- Transport layer supports two services - Reliable (TCP), and Unreliable (UDP)
- Two types of sockets:
 - ① **Stream Socket (SOCK_STREAM)**: Reliable, connection oriented (TCP based)
 - ② **Datagram Socket (SOCK_DGRAM)**: Unreliable, connection less (UDP based)

Socket API

- `int s = socket(domain, type, protocol);` - Create a socket
 - `domain`: Communication domain, typically used `AF_INET` (IPv4 Protocol)
 - `type`: Type of the socket - `SOCK_STREAM` or `SOCK_DGRAM`
 - `protocol`: Specifies protocols - usually set to 0 – **Explore!**
- `int status = bind(sockid, &addrport, size);` - Reserves a port for the socket.
 - `sockid`: Socket identifier
 - `addrport`: `struct sockaddr_in` - the (IP) address and port of the machine (address usually set to `INADDR_ANY` chooses a local address)
 - `size`: Size of the `sockaddr` structure

struct sockaddr_in

- `sin_family` : Address family, `AF_INET` for IPv4 Protocol
- `sin_addr.s_addr`: Source address, `INADDR_ANY` to choose the local address
- `sin_port`: The port number
- We need to use `htons()` function to convert the port number from **host byte order** to **network byte order**.

```
struct sockaddr_in serveraddr;  
int port = 3028;  
serveraddr.sin_family = AF_INET;  
serveraddr.sin_addr.s_addr = INADDR_ANY;  
serveraddr.sin_port = htons(port);
```

Host Byte Order to Network Byte Order - Why?

- Little Endian and Big Endian System

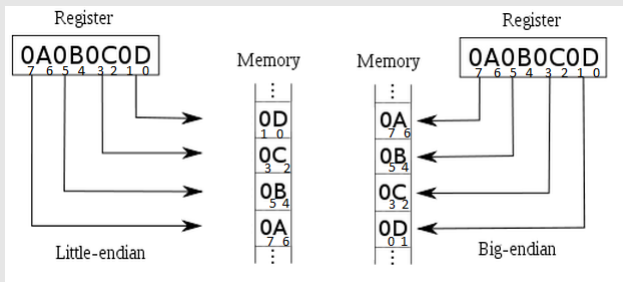

Host Byte Order to Network Byte Order - Why?

- Little Endian and Big Endian System

Host Byte Order to Network Byte Order - Why?

- Little Endian and Big Endian System

- Assume a communication from a Little Endian to a Big Endian System or vice-versa!**

Host Byte Order to Network Byte Order - Why?

Listen and Accept a Socket Connection

```
struct sockaddr_in cli_addr;  
listen(sockfd,5);  
clilen = sizeof(cli_addr);  
newsockfd = accept(sockfd,(struct sockaddr *) &cli_addr,  
&clilen);
```

- **Active Open and Passive Open**

- The server needs to announce its address, remains in the open state and waits for any incoming connections - Passive Open
- The client only opens a connection when there is a need for data transfer - Active Open
- Connection is initiated by the client

Data Transfer through Sockets

① For SOCK_STREAM:

- `read(newsockfd,buffer,255);`
- `write(newsockfd,‘‘I got your message’’,18);`

② For SOCK_DGRAM:

- `recvfrom(sock,buf,1024,0,(struct sockaddr *)&from,&fromlen);`
- `sendto(sock,‘‘Got your message’’,17,0,(struct sockaddr *)&from,fromlen);`

Putting it All Together
